## **DISCLAIMER**

---

PRESTO, the included help manuals, and sample data files are made available free on an "as is" basis with no implied or expressed warranties. The user must assume the entire risk of using the tool. Although PRESTO has been tested with statewide data, good engineering practice requires that all work completed using this program should be checked with alternative methods.

## **Executive Summary**

---

The objective of the Wisconsin Department of Natural Resources' (WDNR) Bureau of Water Quality is to protect and enhance Wisconsin's water resources. As part of this, the Water Quality Modeling Technical Team strives to provide the public with timely information on water quality and decision support tools to guide management decisions. Phosphorus, which is a nutrient that can impair water quality, is the focus of several new water quality regulations in Wisconsin. Reduction of phosphorus concentrations within Wisconsin waterways requires identification of the sources of phosphorus. To assist in achieving phosphorus reductions, a state-wide screening tool was developed that identifies the dominant source (point vs. nonpoint) of phosphorus within a watershed. The regulatory catalysts for this work include:

- Chapter NR 217, Wisconsin Administrative Code which controls the point source effluent limits for phosphorus;
- The Federal Clean Water Act which requires the prioritization and targeting of TMDLs in order to set limits on pollutant loading.

The Pollutant Load Ratio Estimation Tool (PRESTO) is a statewide GIS-based tool that compares the average annual phosphorus loads originating from point and nonpoint sources within a watershed. The comparison provides a screening tool for industrial and municipal dischargers to determine one of the conditions of eligibility for adaptive management as part of ch. NR 217, Wis. Adm. Code. The watershed adaptive management option described in s. NR 217.18, Wis. Adm. Code, allows a point source to achieve compliance with applicable water quality based effluent limits needed to achieve the phosphorus water quality standards criteria in a more economically efficient manner, through comprehensively managing point and nonpoint sources of phosphorus in the watershed. Under this option the permitted facility is given interim effluent limits and must work with watershed partners to implement a watershed adaptive management plan. PRESTO also helps industrial and municipal dischargers determine if water quality trading is a feasible option within their watershed. PRESTO provides dischargers with a consistent and transparent method for determining regulatory compliance and allows the DNR to make fast and effective permitting decisions to aid in the permit streamlining effort.

PRESTO was used to evaluate approximately 652 permitted industrial and municipal outfall locations throughout the state. The ratio of point to nonpoint source phosphorus loads for each evaluated facility was calculated. For 82% of the facilities evaluated (533 of 652), point sources of phosphorus were less than 50% of the total annual phosphorus load, thus satisfying one of the eligibility conditions for adaptive management.

## **1.0 INTRODUCTION**

---

While phosphorus (P) is an essential nutrient for plant growth, excess phosphorus can accelerate eutrophication of water bodies, increasing the frequency of algal blooms that can negatively impact both human and ecosystem health. Locating and effectively managing the sources of phosphorus within a watershed is critical for improving water quality. The most general categories of phosphorus sources are waste water treatment facilities (hereafter called “point sources” because they discharge to surface waters at a defined point) and nonpoint sources, which include runoff from diffuse sources across the landscape. The relative significance of point and nonpoint sources of phosphorus vary substantially among watersheds, which means there is no “one-size-fits-all” approach to managing phosphorus.

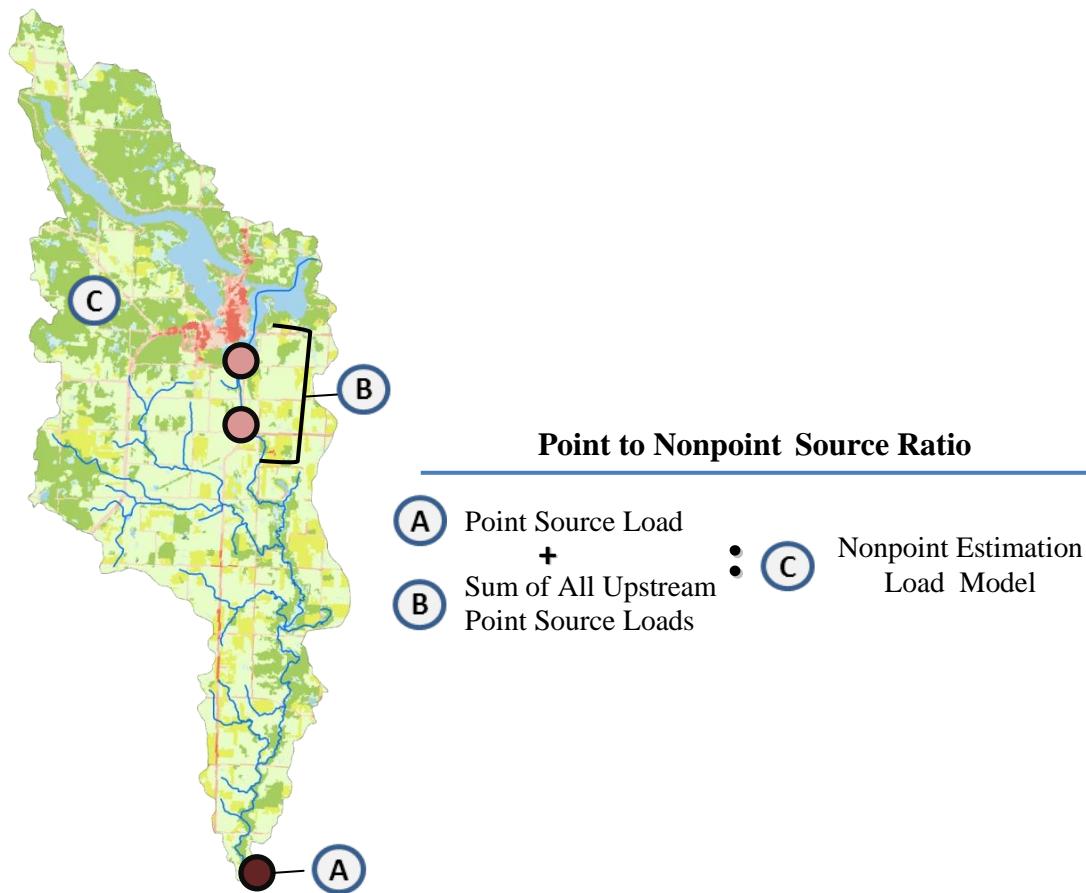

The Wisconsin Department of Natural Resources (WDNR) has developed a spatial toolset called the Pollutant Load Ratio Estimation Tool (PRESTO) to compare a watershed’s average annual point and nonpoint phosphorus loads (Figure 1). PRESTO was designed to be easily modified, transparent to the end user, and provide a consistent result based on readily available datasets. PRESTO performs three basic functions: watershed delineation, nonpoint source loading estimation, and point source loading aggregation. The PRESTO outputs include a delineated watershed, watershed land cover composition, the estimated average annual nonpoint source and measured point source phosphorus loads (pounds per year), and the ratio of point to nonpoint phosphorus at a watershed outlet.

The comparison provides a screening tool for industrial and municipal dischargers to determine whether they have fulfilled s. NR 217.18(2)(b), Wis. Adm. Code, one of the conditions to determine eligibility for adaptive management. Adaptive management allows a point source to control phosphorus discharges from other point and/or nonpoint sources to achieve compliance with applicable phosphorus water quality criteria in s. NR 102.06 in the most economically efficient manner possible. PRESTO also helps industry and municipalities determine if water quality trading is a feasible option within their watershed.

While the main use of PRESTO is in support of NR 217, it also has other more general applications. The tool can be used solely for watershed delineation. The methods used in PRESTO are such that delineations performed for locations throughout the state will be consistent, following the previously established Watershed Boundary Dataset HUC12 unit boundaries (USGS and NRCS, 2011). Also, instead of using PRESTO delineated basins, the model can accept custom user-specified basins on which to perform the nonpoint and point source calculations. One example of the use of this function would be to summarize the point and nonpoint phosphorus loads for every HUC12 in Wisconsin.

The following report provides information on the model inputs, methodology, outputs and limitations; it also describes the statewide model validation and presents model output for over six hundred permitted outfalls throughout the state. Throughout the report phosphorus will refer to total phosphorus which includes both dissolved and particulate

forms of phosphorus. Section 2 of this report describes the framework upon which PRESTO is built. Section 3 specifies the standard and user-defined inputs to PRESTO. Section 4 explains the methodologies behind the watershed delineation and nonpoint source loading processes. Section 5 describes the outputs generated by PRESTO. The model limitations are outlined in Section 6. Section 7 illustrates the statewide validation of the model methodologies. Section 8 describes the results of the statewide outfall analysis. The appendices contain additional validation information, PRESTO scripting details, a statewide analysis table and table of permitted outfall locations excluded from this analysis. A companion report, the PRESTO User Manual, outlines in detail, the necessary steps to install and run PRESTO with default and user-supplied data.

**Figure 1:** PRESTO Point to Nonpoint Source Phosphorus Load Ratio Calculation

## **2.0 PRESTO FRAMEWORK**

---

PRESTO is written in the Python scripting language, which has been adopted as the native scripting language for ArcGIS 10, replacing Visual Basic in the command line and map algebra environments. Python was chosen as the scripting language for PRESTO not only because of the ease of integration with ArcGIS 10, but because of its transparency, availability, and power. ESRI aptly describes Python as “free, cross platform, open source, stable, mature, simple, and powerful” – with this in mind, PRESTO is designed to be easily customizable and transparent to users with only a basic knowledge of scripting. Because PRESTO performs a large number of distinct functions, these functions are divided into separate libraries (script files) for the ease of reading the script and making changes to the various subroutines in the tool.

The PRESTO interface was developed within the ArcGIS 10 Desktop framework and requires the Spatial Analyst extension. Additional system requirements are presented in the accompanying User Manual. PRESTO is packaged with an ESRI ArcMap document (*PRESTO 1.1.mxd*), toolbox (*PRESTO 1.1.tbx*), and six folders containing the model scripts and default input datasets. Even though PRESTO is comprised of several Python script files, the user needs only to open the PRESTO ToolBox within ArcMap to run PRESTO. The input screen for PRESTO requires the user to specify their input data and other datasets required for the tool to run. PRESTO can be run with only the datasets included in the tool package, though it allows the user to specify custom datasets as necessary. Detailed descriptions of the tool inputs and required datasets are included in the User Manual. The tool runs within the ArcGIS window and inserts the output files into the open ArcMap document.

## **3.0 PRESTO DATA SOURCES**

---

PRESTO requires up to five spatial datasets in order to accomplish its core functions: watershed delineation, nonpoint source loading, and point source loading aggregation. PRESTO is packaged with a default set of input datasets with which the tool was designed to work. To allow for greater flexibility, PRESTO allows the user to load other datasets into the tool, provided they follow a similar attribute structure.

There are five statewide inputs included with PRESTO:

Digital Elevation Model (DEM): A DEM is used to subdelineate the area within the most downstream subbasin (e.g., HUC12) containing the user defined outfall location or delineation point. The DEM is also necessary to determine where the water drains as it leaves a subbasin. To ensure that delineation coincides with known flow paths, the DEM is hydrologically modified by filling sinks, burning in the streams, and building walls. Stream burning ensures that flow is forced to those cells that correspond to the true locations of streams; this is especially important in flat areas where the DEM may not accurately represent stream locations. In addition to developing preferred stream paths,

walls were created within the DEM ensuring that pre-defined subbasin (HUC12) boundaries are always used as part of the upstream watershed delineation. Building walls involves raising the elevation of the DEM cells along the subbasin boundaries in order to prevent flow across them.

**Hydrologic Network:** The hydrologic network provides PRESTO with polylines to which outfall/delineation points can be snapped and then linked with the DEM's flow accumulation grid. The hydrologic network is also necessary for one of the nonpoint source loading calculation methods.

**Subbasin Boundaries:** Subbasin boundaries can be used to provide consistency between the delineations that are used by other sources and ones derived by PRESTO. In addition, user-defined subbasins can be used as the basis for summarizing point and nonpoint loads.

**Outfall or Delineation Points:** These points define the spatial locations from which the delineation and subsequent load calculations occur. For the Wisconsin outfall file, the outfall points represent the location where a facility's end-of-pipe discharge enters a receiving water. The dataset should contain attribute information for each outfall including a unique numeric identifier, the receiving water to which the outfall discharges, and the annual effluent load per year.

**Land cover:** The land cover dataset is used by the nonpoint source loading calculation methods. Additional information regarding the use of the land cover dataset for the nonpoint calculations can be found in Section 4.0.

---

## 4.0 PRESTO METHODOLOGY

PRESTO performs two routines: (1) delineation of a drainage basin upstream of a point, and (2) application of a spatially-explicit nonpoint source phosphorus model (or models) to a drainage basin polygon. When running PRESTO, it is possible to perform both of these functions in sequence, or either of them individually.

### 4.1 *Delineation*

While tools exist to delineate watersheds within GIS (e.g., ArcHydro), one of the main goals of the delineation function within PRESTO was to have a method that was consistent throughout Wisconsin and conformed to the standard HUC12 boundaries where appropriate. The delineation method employed by PRESTO is novel and is distinguished from conventional batch watershed delineation algorithms in two primary ways: (1) short processing times and (2) minimal requirements for data preprocessing. PRESTO is capable of rapid delineation of watersheds using a DEM with burned streams, a corresponding set of stream polylines, and a set of hierarchical subbasins. These

advantages are achieved through a relatively complex delineation algorithm, which is displayed graphically in Figure 2.

The delineation algorithm can be summarized in five steps illustrated in Figure 2:

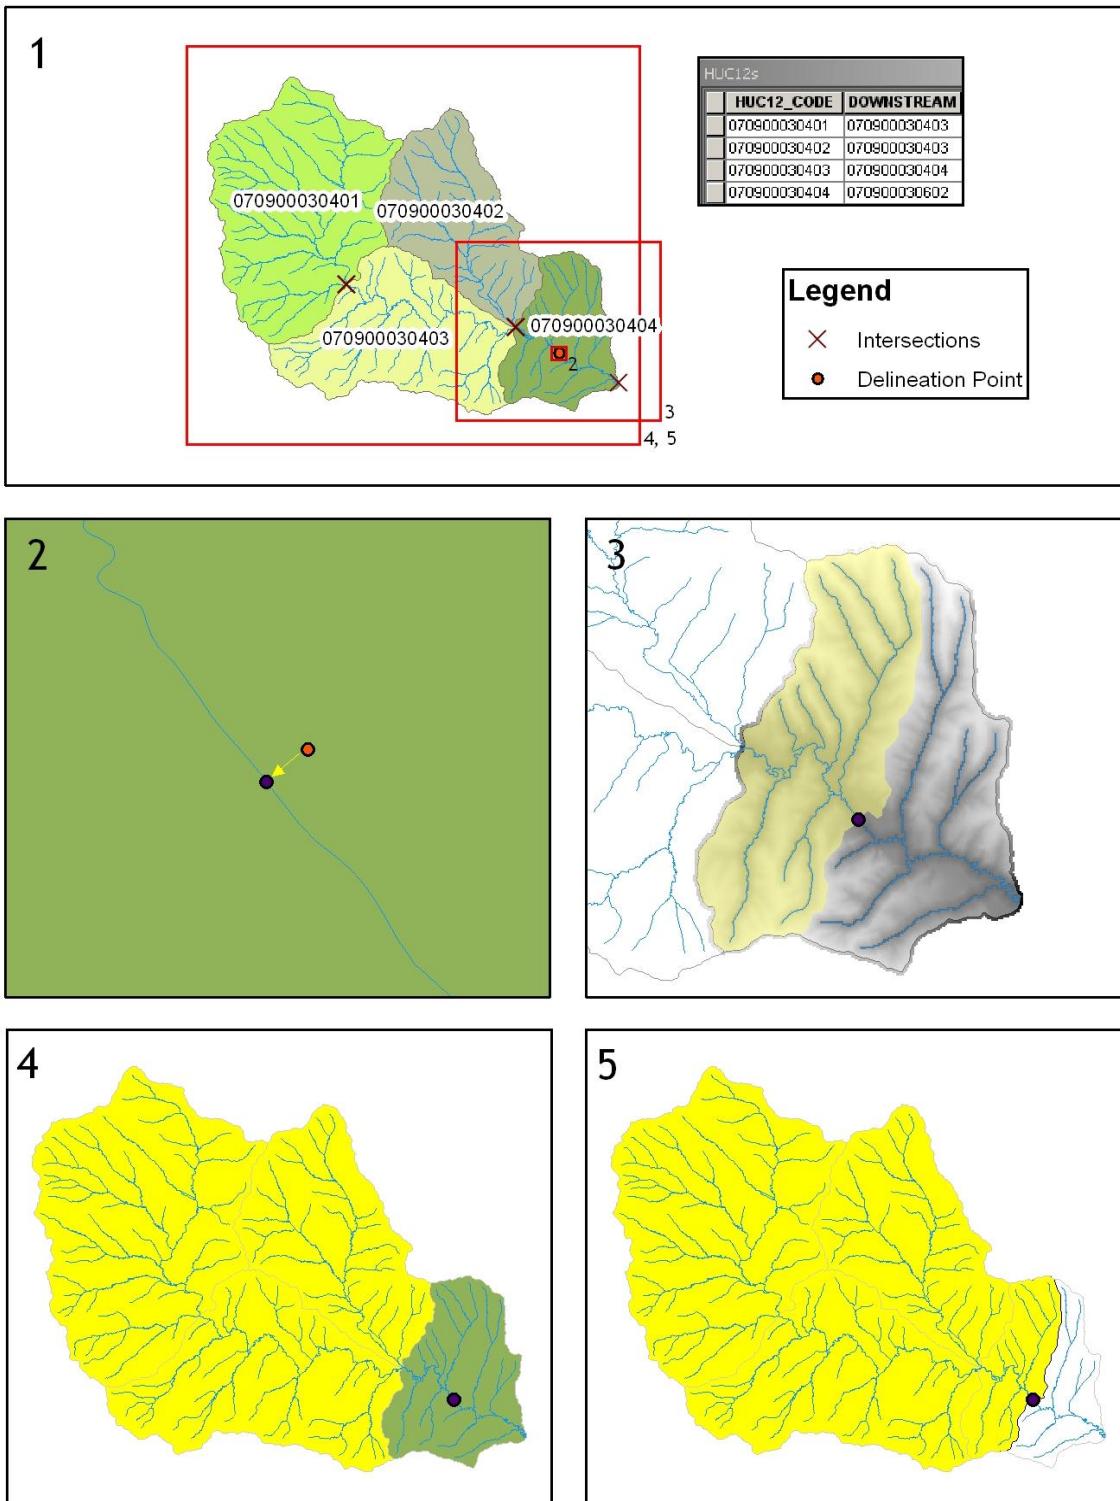

1. Subbasin topology (how each subbasin connects to another) is created using upstream-downstream basin attributes and intersecting stream lines with subbasin boundaries;
2. The outfall point is snapped to a stream;
3. The upstream section of the subbasin containing the outfall point, or “**inner watershed**”, is derived using terrain analysis;
4. Upstream subbasins are identified and joined to form an “**outer watershed**”;
5. The inner watershed and outer watershed are joined and dissolved to create the “**total watershed**”.

Rapid delineation is achieved by performing time-consuming terrain analysis on only a small area (sub-HUC12 by default), then conforming to existing basin boundaries for the upstream portions of the watersheds. The tool was designed to use the HUC12 basins, with average areas of 30 square miles.

## **4.2 Nonpoint Source Loading**

PRESTO uses the land use classifications and drainage lines within a specific watershed to calculate the nonpoint source phosphorus loading. The nonpoint source phosphorus loading is calculated using three different methods: land use specific export coefficients, multiple regression model #1, and multiple regression model #2. This section describes the basic structure of each method. The relative merits of the three approaches are discussed in Section 7.

The first method uses land-cover-specific export coefficients from the Wisconsin Lake Modeling Suite (WiLMS) software which were derived from values published in Panuska and Lillie, 1995 and Corsi et al, 1998 and values from MPCA, 2004 (Table 2). Nonpoint phosphorus loads are calculated by multiplying the area of each land cover type in a watershed by an export coefficient for each type. Low, high, and most likely export coefficients are used to give low, high, and most likely annual loading values. Table 1 displays the NLCD land cover categories and their corresponding export coefficients.

**Figure 2:** Delineation Process

**Table1:** Phosphorus export coefficients by land cover category.

LC ID	Description	P Low	P Most Likely	P High	Source
		lb/mi <sup>2</sup> (kg/ha)	lb/mi <sup>2</sup> (kg/ha)	lb/mi <sup>2</sup> (kg/ha)	
11	Open Water	0 (0)	0 (0)	0 (0)	NA
21	Developed, Open Space	57 (0.1)	171 (0.3)	286 (0.5)	WiLMS: Pasture/Grass
22	Developed, Low Intensity	29 (0.05)	57 (0.1)	143 (0.25)	WiLMS: Rural Residential (> 1 Ac)
23	Developed, Medium Intensity	171 (0.3)	286 (0.5)	457 (0.8)	WiLMS: Medium Density Urban (1/4 Ac)
24	Developed, High Intensity	571 (1.0)	856 (1.5)	1142 (2.0)	WiLMS: High Density Urban (1/8 Ac)
31	Barren Land	0 (0)	0 (0)	0 (0)	NA
41	Deciduous Forest	29 (0.05)	54 (0.09)	103 (0.2)	WiLMS: Forest
42	Evergreen Forest	29 (0.05)	54 (0.09)	103 (0.2)	WiLMS: Forest
43	Mixed Forest	29 (0.05)	54 (0.09)	103 (0.2)	WiLMS: Forest
52	Shrub/Scrub	43* (0.08)*	74 (0.13)*	123* (0.22)*	MPCA, 2004: Shrubland/Transitional
71	Grassland/Herbaceous	57 (0.1)	97 (0.17)	143 (0.25)	MPCA, 2004: Grassland/Herbaceous
81	Pasture/Hay	57 (0.1)	171 (0.30)	286 (0.5)	WiLMS: Pasture/Grass
82	Cultivated Crops	286 (0.5)	571 (1.0)	1713 (3.0)	WiLMS: Row Crop AG
90	Woody Wetlands	0 (0)	0 (0)	0 (0)	NA
95	Emergent Herbaceous Wetlands	0 (0)	0 (0)	0 (0)	NA

\* Average of Deciduous Forest and Grassland/Herbaceous values

The second method (MR #1) uses a multiple regression model that was modified from a version originally developed for the Wisconsin Buffer Initiative (Diebel, *et. al.* 2009). In the model, grassland along streams is associated with more nonpoint phosphorus loading, and may represent phosphorus from grazing animals. Forest in the stream watershed is associated with less phosphorus, and can be considered the inverse of cropland. Stream density represents the capacity of the landscape to transport phosphorus. The validation analysis described in Section 7 showed that Model #1 is the best predictor of measured phosphorus loads statewide.

$$\log_{10}(P) = -0.01284 + 0.12966 * \sqrt{G} + 4.80482 * \frac{1}{F + 4} + 1.57791 * \ln(S + 1)$$

Where

- P = average annual total phosphorus load in kg/km<sup>2</sup>
- G = % grassland in 30 meter zone around 24k streams
- F = % forest in the watershed
- S = stream density or the total length of 24k streams in watershed divided by the watershed area

The third method uses multiple regression model #2, which was developed from the same dataset as MR #1, but using a different combination of variables. The land cover variables in MR #2 are cropland and urban land, whose connections to phosphorus loading are more well-defined than the variables in MR #1. Despite its more intuitive structure, the predictive ability of MR #2 is somewhat less than MR #1, which is why both models are included in PRESTO.

$$\log_{10}(P) = 0.241141 + 0.006127 * C + 0.127819 * \ln(U + 1) + 1.666141 * \ln(S + 1)$$

Where

- P = average annual total phosphorus load in kg/km<sup>2</sup>
- C = % cropland in the watershed
- U = % urban land in the watershed
- S = stream density or the total length of 24k streams in watershed divided by the watershed area

As with the export coefficients (Table 1), both multiple regression models can also be used to predict low, high, and most likely load estimates. Most likely values are derived directly from the equations above. Low and high load estimates account for uncertainty in the actual effects of the model variables and are calculated as the bounds of the 80% prediction interval from the regression equation. This means that we can be 80% confident that the load will fall within that range.

### **4.3 Point Source Loading**

Annual permitted municipal and industrial point source loads have been calculated from permitted facilities with effluent flow and phosphorus monitoring records stored in the WDNR's SWAMP database. To calculate the annual phosphorus loads, first the average annual discharge and phosphorus concentration were calculated from the specific year's monitoring data. There were several instances in which missing records (usually phosphorus, rarely flow) were replaced with estimated values. Some permittees, typically smaller facilities, were not required to collect routine phosphorus data. In those instances, an estimated value based on the most recent year's monitoring record was used.

$$\text{Annual Discharge (MGD)} = \frac{\text{Measured Total Flow (MGD)}}{\# \text{ of Discharge Days}}$$

$$\text{Annual P (mg/L)} = \frac{\sum(\text{P Sample Concentrations (mg/L)})}{\# \text{ of Samples}}$$

$$\text{Annual P Mass (lbs)} = \text{Annual Discharge} * \text{Annual P Concentration} * 8.344 * 365.25$$

The annual loading data was joined to the georeferenced active outfalls coverage stored within WDNR's SDE spatial server. In the instances where a permit had multiple outfalls, the loads were summed together to represent a single load per permitted site. At the time of this effort, there were 722 permitted outfalls throughout Wisconsin that were georeferenced and had phosphorus monitoring data.

To define the point source loading, PRESTO calculates the total loading upstream from a particular point source and exports that value along with the loading at the location of interest (if applicable). These results and the nonpoint source load are used to calculate the ratio of point to nonpoint source loads at each outfall location or user-defined subbasin.

## 5.0 PRESTO OUTPUTS

---

PRESTO applies the methodology in Section 4.0 to determine the ratio of the point source loading to the nonpoint loading, which is dependent on the nonpoint estimation model that is used. In conjunction with the phosphorus point to nonpoint source ratio, the PRESTO outputs information related to the watershed's land cover and other calculations related to the nonpoint source (Table 2).

**Table 2:** PRESTO Output Categories

Output Category	Output Sub-Category
Watershed Characteristics	Basin Area
	Stream Density
	% Grassland within 30 meters of stream reach
Land Cover	% composition of each land cover type in the watershed
Point Load	P load of all upstream point sources
	P load of point source
Nonpoint Estimation Model – Export Coefficient (EC)	EC Model P Load Estimate (most likely)
	ECModel P Load Estimate (lower bound)
	ECModel P Load Estimate (upper bound)
	ECModel Total Load (most likely estimate load, point source load, all upstream point source load)
	PS:EC NPS Load Ratio (%)
	Export Coefficient Model P Yield Estimate
Nonpoint Estimation Model – Multiple Regression #1 (MR #1)	MR #1 Load Estimate (most likely)
	MR #1 Load Estimate (lower bound)
	MR #1 Load Estimate (upper bound)
	MR#1 Total Load (most likely estimate MR#1 load, point source load, all upstream point source load)
	PS:MR #1 NPS Load Ratio (%)
	Multiple Regression Model #1 P Yield Estimate
Nonpoint Estimation Model – Multiple Regression #2 (MR #2)	MR #2 Load Estimate (most likely)
	MR #2 Load Estimate (lower bound)
	MR #2 Load Estimate (upper bound)

	MR#2 Total Load (most likely estimate MR#2 load, point source load, all upstream point source load)
	PS : MR #2 NPS Load Ratio (%)
	Multiple Regression Model #2 P Yield Estimate

The attribute information in Table 2 can be output in three spatial forms, as specified by the user:

- **Points** – A point shapefile containing the locations of the snapped outfall/delineation points, with model outputs as attributes
- **Combined Watersheds** – A single polygon shapefile containing polygons representing delineated watersheds, with model outputs as attributes
- **Individual Watersheds** – A series of polygon shapefiles containing a single polygon representing a delineated watershed, with model outputs as attributes

## 6.0 PRESTO LIMITATIONS

---

PRESTO was designed for the purpose of supporting NR 217 and TMDL prioritization at a statewide level. While several of its functions may have other applications, users should be aware of the following limitations:

- The most downstream HUC12 typically requires sub-delineation using a 30-meter DEM (default dataset). The subwatershed delineation is only as accurate as the DEM resolution and burned hydrology, though PRESTO does allow the user to integrate more detailed datasets if they are available.
- PRESTO can only be applied for watersheds fully within Wisconsin. All input data layers are clipped at the Wisconsin border even though some watersheds extend into neighboring states.
- PRESTO may not be very accurate for watersheds with significant internally drained areas because the nonpoint load estimation assumes that the entire drainage contributes.
- Application to highly urban areas may lead to inaccurate results because of the highly modified drainage patterns indicative of urban areas. Landscapes that drain to stormwater systems export pollutants differently than those that rely primarily on overland runoff. PRESTO's nonpoint estimation models were developed in landscapes with a small urban land cover component.
- The watershed delineation may not accurately delineate small watershed areas in very flat regions due to the resolution of the default DEM.

- The nonpoint source load estimation methods predict loading under average climatic conditions and therefore will not accurately predict loading in years with extremely high or low runoff.
- The applicability of PRESTO for subwatershed prioritization (HUC12 or smaller) cannot be verified due to lack of extensive monitoring data within watersheds of that scale.

## **7.0 PRESTO STATEWIDE VALIDATION**

---

Each nonpoint estimation model used in PRESTO was developed based on measured phosphorus load data from throughout Wisconsin. Therefore, these methods should give reasonable results when applied to watersheds within the state. To verify this, the three PRESTO nonpoint estimation models were compared to measured annual loadings at numerous points throughout the state. This exercise demonstrates the validity of the methods, reveals which method performs best statewide, and which nonpoint estimation models are more appropriate for watersheds with different characteristics.

### ***7.1 Measured Phosphorus Loading***

The measured annual phosphorus loading values were obtained from two main sources. The first was a USGS publication (Corsi et. al., 1997) that reported unit-area loads from small watersheds in Wisconsin. This publication presented median annual total phosphorus loads at 52 sites throughout the state. The sites represented watersheds with data from 1975 to 1996, drainage areas less than 200 square miles, one or more years of continuous data, and less than 15% of the total monitored yearly load attributable to point sources.

The second source of measured annual phosphorus loading was data developed by the USGS to support SPARROW model calibration (Saad et. al., 2011). This dataset consisted of mean annual phosphorus loads that were detrended to a 2002 base year. These annual loads were determined using Fluxmaster and consisted of data from 1970 to 2007. Individual measurement locations had between 27 and 1038 phosphorus concentration measurements that were used in the loading calculation. The process of detrending helps “compensate for differences in the length and amount of monitoring data among sites, and minimizes the inherent noise introduced by year-to-year variations” (Saad et. al., 2011).

While these two datasets were not developed in exactly the same way, it was the best information available for this analysis. Therefore, the inconsistencies between datasets can be included as a source of uncertainty in this validation analysis.

In order to validate the multiple regression models against an independent data source, any measured load location that was used in the development of the multiple regression analysis was excluded from the validation dataset. The export coefficients developed in Panuska and Lilly, 1995, (and used in WiLMS) used phosphorus loads from various

studies throughout the state. Some of the data used to determine those loads, and thus the export coefficients, may overlap with some of the data being used for the validation. Without knowing exactly what data overlaps, it was not possible to exclude it from the validation dataset.

## **7.2 Validation Analysis**

PRESTO was used to delineate drainage basins for each of the measured data locations. After eliminating the known monitoring sites used in the development of one the nonpoint estimation models, 77 were selected to measure how well the three nonpoint methods performed (Figure 3).

In addition to the drainage basin delineation, PRESTO also calculated the annual nonpoint phosphorus load using each of the three nonpoint estimation methods for each delineated drainage basin and summed the total average annual point loads (upstream point load plus primary point load) using the average point load from 1995-2009. Again, since this timeframe does not necessarily match that of the measured data, this also contributes to the uncertainty in this analysis. The upstream point source loads were added to the nonpoint loads and then compared to the measured loads. This comparison assumes there is no loss or gain of phosphorus within the stream channels, presenting another source of uncertainty in the analysis.

## **7.3 Validation Statistics**

Several goodness-of-fit measures were used to determine which nonpoint estimation method predicted loads that best corresponded with measured loads; they included graphical, Nash-Sutcliffe, percent bias, ratio of root mean square error to standard deviation, average percent error, and coefficient of determination as suggested by Moriasi et al, 2007. Since each measure has its own strengths and weaknesses, looking at several measures provides a more holistic view of model performance.

Figure 4 is a plot of the observed versus “most likely” predicted annual phosphorus loads for each of the three nonpoint methods. This plot reveals that, in general, the larger the annual load the larger the error, though with the great range of values, it is difficult to visualize the performance of the models at low annual load values.

Since there was a large scale range of the data, it was also plotted on a log-log scale shown in Figure 5. This type of plot is better at displaying percent differences of the predicted values from observed. This plot now shows less variability in the larger loads and more in the smaller loads. Both this and the previous plots show that MR #2 tends to overpredict, while the other two methods appear to have the tendency to over- and under-predict.

Plots such as figures 4 and 5 are useful to visualize the data; but to more objectively evaluate the goodness-of-fit of each model, several statistics are presented in Table 3.

**Table 3:** Statewide fit statistics.

	Export Coefficient	MR #1	MR #2
<b>Nash-Sutcliffe</b>	0.64	0.81	-0.11
<b>Percent Bias</b>	23%	-17%	69%
<b>RSR (RMSE/SD)</b>	0.60	0.43	1.05
<b>Average % Error</b>	47%	-6%	113%
<b>R<sup>2</sup></b>	0.88	0.83	0.89

The fit statistics calculated in Table 3 show that MR#1 gives the best results in all measures except coefficient of determination, though the value is not significantly different than for the other two models.

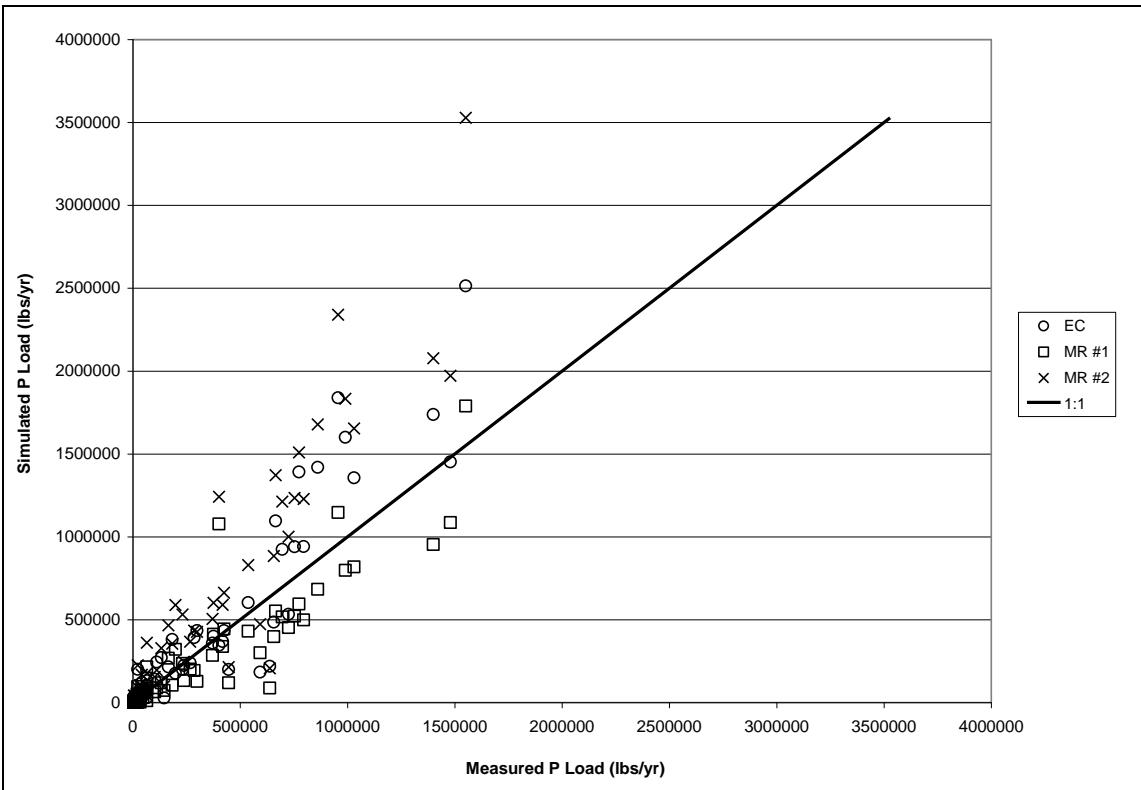

In addition the fit statistics were calculated on subsets of the data according to ecoregion, drainage area, stream density, and percentages of land use in agriculture, forest and urban. Those results are shown in Tables A1-A10 Appendix A. See Figure 6 for a map of Wisconsin ecoregions, based on the Level III classification with the addition of the Central Sands region. Data plots of fit statistics and error versus various watershed metrics are shown in Appendix A Figures A1-A9.

## 7.4 Discussion

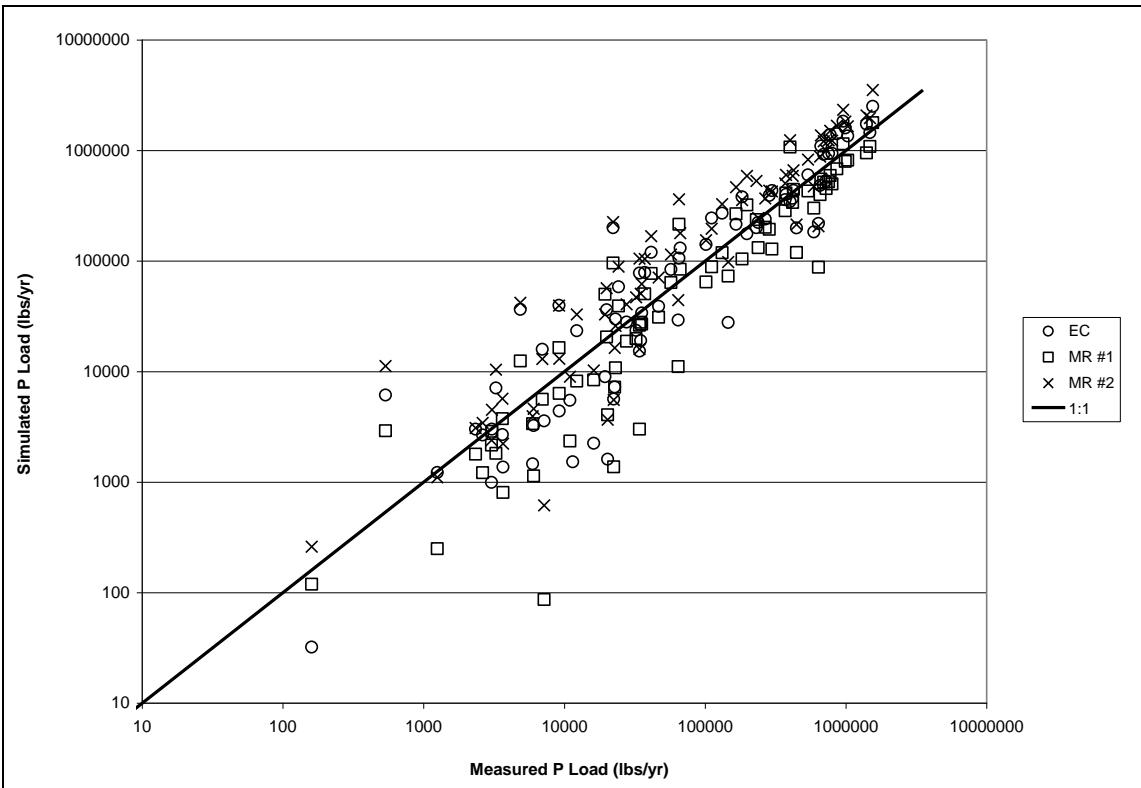

The fit statistics show that, in general, the MR #1 model performs best statewide, with the land use export coefficient method the next best. The MR #2 model generally over-predicts loads at larger drainage areas, though when the data are log-transformed, the fit statistics are comparable to the other two methods. The MR #1 and export coefficient models perform better at higher stream densities than the MR #2 model and similarly for drainage basins where agriculture is dominant, though stream density is slightly positively correlated to percent agriculture in these basins. There are fewer drainage areas that are dominated by forest and urban, but all models perform well in forested basins while the MR #2 model performs best in highly urbanized basins, which is expected since it uses percent urban area in the basin in its calculation. None of the methods simulated phosphorus loading in the Central Sands area well, though there were only 4 validation points within this ecoregion. The export coefficient model performs best in the Driftless Area with little difference between models in the remaining ecoregions.

**Figure 4:** Measured versus “most likely” simulated annual phosphorus loads.

**Figure 5:** Log measured versus log simulated annual phosphorus loads

**Figure 6:** Validation Points per Wisconsin Ecoregion

## 8.0 VALIDATION OF SUBWATERSHED PRIORITIZATION

In addition to calculating the ratio of point to nonpoint source contributions based on a specified outfall or delineation point, PRESTO can also be applied to pre-defined subwatersheds such as the PRESTO default HUC12 subwatersheds. Each individual subwatershed serves as the spatial unit for modeling and analysis and therefore point and nonpoint loads are calculated for each subwatershed. One application for this type of analysis would be a screening level approach towards identifying subwatersheds with the largest pollutant loads.

To validate the applicability of the different nonpoint source estimation models in targeting phosphorus export from subwatersheds within a large drainage, two of the three

nonpoint estimation models (export coefficient and MR #1) used in PRESTO were compared to the results of a data intensive, process based model called the Soil and Water Assessment Tool (SWAT). The MR #2 model was omitted from this analysis because the estimated loads were statistically less relevant than the other two methods when evaluated against statewide monitoring data. The Eau Claire River Watershed in western Wisconsin was used for the comparison of SWAT and the PRESTO nonpoint estimation models since the SWAT model had already been applied there. Given the process-based natured of the SWAT model, the detail of the input data, and rigor of calibration, we consider the SWAT model results to be the best information available. The Eau Claire Watershed is an 800 square mile watershed with 37 subwatersheds (average size 22 mi<sup>2</sup>).

When comparing the two PRESTO nonpoint source estimation methods against SWAT, the MR #1 model estimated a watershed outlet load that most closely matched the SWAT simulated load. While the MR #1 model most closely matched the SWAT simulated phosphorus load at the watershed outlet, the individual subwatershed loads calculated by the MR #1 model did not have the same spatial pattern as the SWAT model results (Figure 7). The export coefficient model more closely matched the spatial pattern of the SWAT model; however, the annual total nonpoint source load was overestimated compared to the SWAT model results. These same trends held true in other SWAT modeled watersheds including the Mead Lake and Red Cedar watersheds.

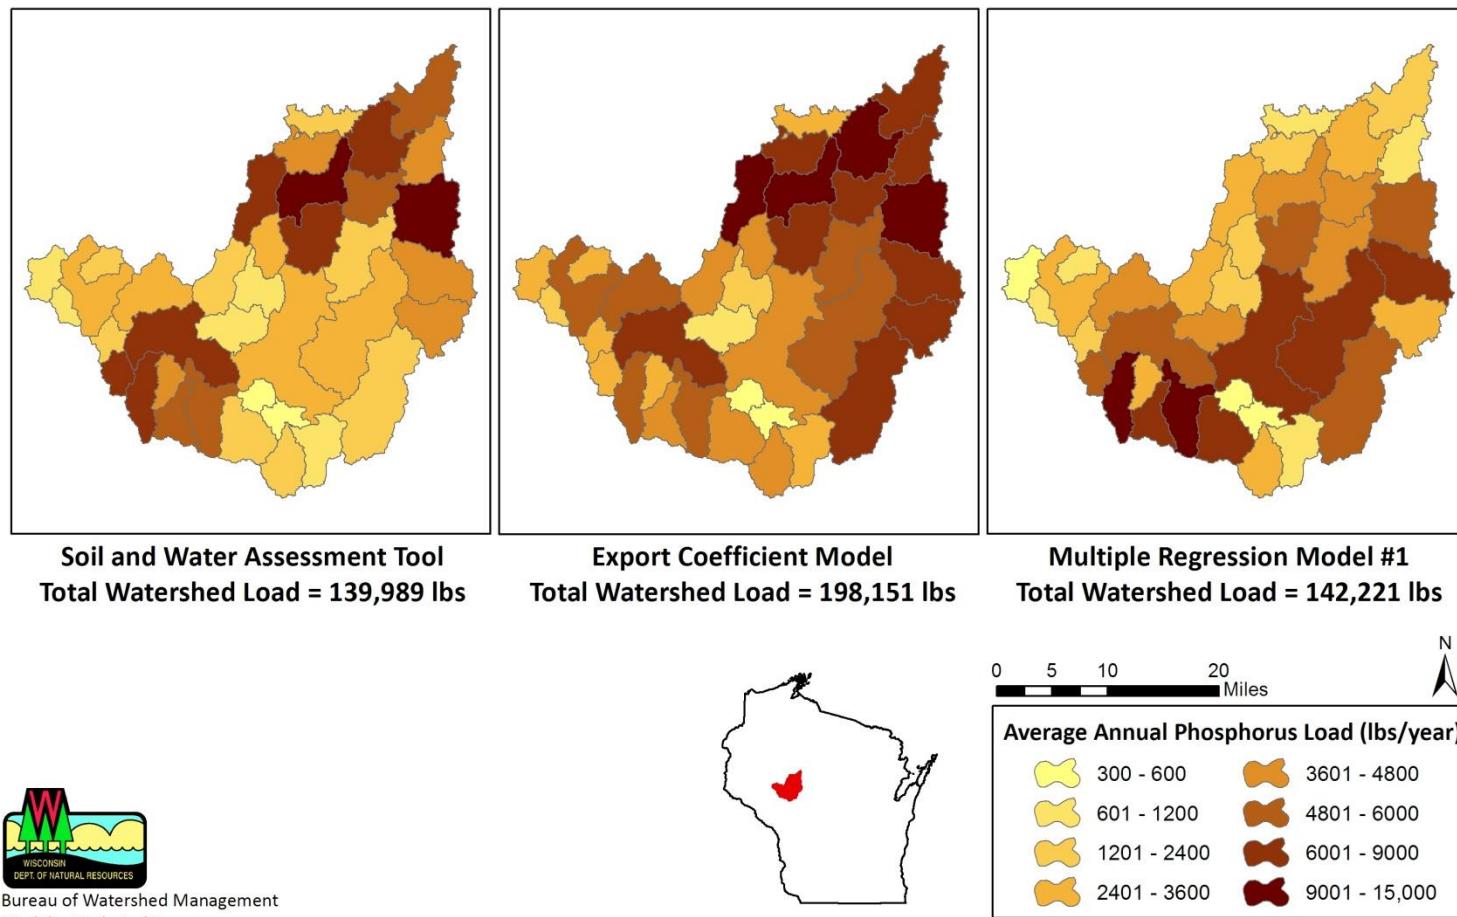

The results of this analysis indicate that without detailed monitoring data to verify phosphorus export from both the larger basin and its contributing subwatersheds, the use of PRESTO for targeting nonpoint source reduction efforts toward subwatersheds with high phosphorus export may be inappropriate. At the watershed outlet, the MR #1 produced a similar phosphorus load as the SWAT model, indicating that when compared to a multi-objective calibrated SWAT model, MR #1 is best choice of the three models nonpoint source estimation for watersheds not dominated by urban land use.

## **9.0 PRESTO STATEWIDE ANALYSIS**

---

One of the main objectives of the PRESTO development was to provide industrial and municipal dischargers throughout Wisconsin the information necessary to determine if they satisfy one of the preconditions for adaptive management as stated in Wisconsin administrative code NR 217. Appendix B presents the point to nonpoint source phosphorus load ratio for every georeferenced permitted outfall in Wisconsin for which effluent monitoring data was available (excluding some in the Milwaukee River Basin in the highly urbanized area). If the facility and all permitted upstream point sources within their watershed contribute less than 50% of the phosphorus loading at the outfall point, then the facility has fulfilled NR 217.18(2)(b) and may be eligible for adaptive management.

Comparsion of Eau Claire River Watershed ( $800 \text{ mi}^2$ ) Phosphorus Loads per Subwatershed  
Using Three Nonpoint Source Estimation Models

**Figure 7:** Comparison of nonpoint estimation models for subwatershed prioritization

## **9.1 Data**

The data used for this analysis are described in Section 3. Some modifications to the original datasets were necessary to enable the tool to delineate the appropriate contributing watershed. The data are listed below along with the modifications made.

- HUC 12 Boundaries: Some of the “Downstream” HUC12 values were modified because errors were found in the original dataset.
- Outfall locations: Some outfall locations were eliminated from the analysis because their contributing watershed extended beyond the state boundary (the input datasets were clipped at the state line) or they were located in Lake Michigan or Lake Superior. In addition, because of the resolution of the DEM and stream drainage network, adjustments were necessary to some of the outfall (end of pipe) locations so that PRESTO would delineate the appropriate contributing watershed. Outfall locations were moved for the following reasons:
  - The outfall was near a stream junction and had to be moved slightly past the junction because of DEM resolution;
  - The outfall discharged to a ditch tributary upstream of its official receiving water and had to be moved to the receiving water.
- Hydrography: orphan reaches and lake/reservoir shorelines were removed.
- Land use: no modifications made for this analysis.
- DEM: no modifications made for this analysis.

## **9.2 Results**

PRESTO was run on the outfall points for each major basin in Wisconsin except those within the densely urban region of the Milwaukee River Basin. These points were omitted from the analysis because of the highly altered drainage pattern (storm sewers, etc.) and is therefore outside the nonpoint source models’ application range. The results of the statewide analysis are shown in Appendix B. They are organized by major drainage basin, then by phosphorus source ratio, then by alphabetical order. Because there is some uncertainty in the output results, plots of the reported point source contribution percentage along with the 80% confidence interval are presented in Appendix B. The delineated contributing watersheds for each point source are in *watersheds.shp* and will also be available on the WDNR’s Surface Water Data Viewer.

According to this screening-level analysis, 533 dischargers (if the lower limit of the confidence interval is used) out of the 652 evaluated would satisfy NR 217.18(2)(b) and may be eligible for adaptive management.

As was mentioned, numerous outfall locations were not evaluated as part of this analysis. First, some points falling within the Milwaukee River Watershed were excluded because of the highly urbanized nature of the lower portion of the basin. In addition, there are many outfalls that discharge into Lakes Michigan and Superior, the Mississippi River and

other waters located along the state boundary. Since the contributing basins at those points contain areas outside the state, they were eliminated from this analysis. Finally, there were also some outfalls that have not yet been geo-located and added to the WDNR outfall GIS layer. The facility outfalls excluded from this analysis are presented in Appendix C along with their receiving water and reason for exclusion.

## **10.0 CONCLUSIONS**

---

The Wisconsin Department of Natural Resources (WDNR) has developed a spatial toolset called the Pollutant Load Ratio Estimation Tool (PRESTO) to compare a watershed's average annual point and nonpoint phosphorus loads. The comparison provides a screening tool for industrial and municipal dischargers to determine whether they have fulfilled NR 217.18(2)(b), one of the conditions to determine eligibility for adaptive management.

PRESTO is written in the Python scripting language, and is run through ArcGIS 10 with Spatial Analyst. It is designed to be easily customizable and transparent to users with even basic scripting skills.

PRESTO can be run with only the datasets included in the tool package, though it allows the user to specify custom datasets as necessary. The default datasets include: 30 meter digital elevation model (DEM), 1:24k hydrologic network, HUC12 subbasin boundaries, statewide georeferenced permitted outfall points, and 2006 statewide land cover.

PRESTO performs two routines: (1) delineation of a drainage basin upstream of a point, and (2) application of a spatially-explicit nonpoint source phosphorus model (or models) to a drainage basin polygon. The delineation method employed by PRESTO is novel and is distinguished from conventional batch watershed delineation algorithms in two primary ways: (1) short processing times and (2) minimal requirements for data preprocessing. PRESTO uses the land use classifications and drainage lines within a specific watershed to calculate the nonpoint source phosphorus loading, which can be calculated using three different methods: land use specific export coefficients, multiple regression model #1, and multiple regression model #2. High, low, and most likely values are calculated for each method providing the user with the understanding of the range of model certainty.

The PRESTO outputs include snapped outfall locations and watershed polygons with the following associated attributes: watershed characteristics, land cover breakdown, aggregated point source phosphorus loading, nonpoint phosphorus load estimations from three methods, and ratios of point to nonpoint phosphorus loading.

As with any model system, PRESTO has limitations related to both the methods employed for estimating the nonpoint source phosphorus loading and the default datasets provided for those calculations. While PRESTO can be employed for uses other than in support of NR217, the user is encouraged to be aware of the limitations for other applications.

To verify the validity of the nonpoint source estimation models used in PRESTO the outputs from the three nonpoint estimation models were compared to measured annual loadings at numerous points throughout the state. This process revealed that the multiple regression model #1 (MR #1) performed the best statewide. The validation also showed that the other nonpoint estimation models may be more appropriate for watersheds with certain characteristics.

The PRESTO results were also compared to results of a more detailed model, SWAT, for a few basins in the state to determine if the PRESTO results were appropriate to use to target specific subbasins for implementation of phosphorus load reduction strategies. The results of this analysis indicate that without detailed monitoring data to verify phosphorus export from both the larger basin and its contributing subwatersheds, the use of PRESTO for implementation targeting of subwatersheds with high phosphorus export may be inappropriate. Further validation with a more detailed monitoring dataset is warranted.

PRESTO (using multiple regression model #1 for nonpoint phosphorus load estimation) was used to evaluate 652 permitted industrial and municipal outfall locations throughout the state. According to this screening-level analysis, 533 dischargers out of the 652 evaluated would satisfy NR 217.18(2)(b) and may be eligible for adaptive management.

PRESTO, the documentation, user manual, model scripts and datasets, and results of the statewide analysis are being made available to both internal and external DNR customers and will be supported by the WDNR Modeling Technical Team.
